I want to take a moment to list a few people who have shaped my pursuit of math. Firstly, thank you Mom and Dad for supporting. Mom, you sat with me at the dinner table teaching me

TABLE OF CONTENTS

LIST OF TABLES

LIST OF FIGURES

Chapter 1

Introduction

Here's where you text starts. You might (but don't have to) have sections like...

... or subsections...

1.0.1 Introduction to the Introduction to the Introduction

To include text in your document, you just type. You don't have to worry about spacing between sentences; LaTeX does that automatically. To start a new paragraph, just insert an empty line.

Here comes the new paragraph. You can include tables, such as Table 2.1, which can also be turned if necessary, as seen, e.g. in Table 2.2. (I think the latter is automatically on its own page; the former will just be put where LaTeX thinks it fits best.)

Chapter 2

Introduction

Here's where you text starts. You might (but don't have to) have sections like...

2.1 Introduction to the Introduction

...or subsections...

2.1.1 Introduction to the Introduction to the Introduction

To include text in your document, you just type. You don't have to worry about spacing between sentences; LaTeX does that automatically. To start a new paragraph, just insert an empty line.

Here comes the new paragraph. You can include tables, such as Table 2.1, which can also be turned if necessary, as seen, e.g. in Table 2.2. (I think the latter is automatically on its own page; the former will just be put where LaTeX thinks it fits

best.)

d	2	3	4	5	6	7	8	9
bound	3.6	8.5	15.8	25.7	38.3	53.5	71.4	92.0

Table 2.1: Bounds in various dimensions d.

To start a new chapter, you don't need to add a page break...

d	2	3	4	5	6	7	8	9
bound	3.6	8.5	15.8	25.7	38.3	53.5	71.4	92.0

Table 2.2: More bounds in various dimensions d.

Chapter 3

The Real Stuff

...LaTeX does that automatically.

3.1 Various Tricks

Here are a few tidbits that came to my mind, in no particular order...

I'm sure most people know about \label and \ref; this feature is enough reason for me to use LaTeX. For example, you might have something like...

Theorem 3.1 (Euler)**.** *Leonhard says* $e^{2\pi i} = 1$.

...which you can then later (or earlier) reference as Theorem 3.1 and you can point to page 5 on which it appears. If you label equations like

$$e^{2\pi i} = 1 \,,\tag{3.1}$$

you can reference them most lazily using (3.1).

There are two ways to define internal macros: `\def` and `\newcommand`. The difference is that the former overwrites any possibly existing command, where as the latter induces a LATEX complaint if you're redefining an existing command (in which case you should use `\renewcommand` instead). Since I'm lazy, I tend to use `\def`, with one important exception: `\newcommand` allows you to use arguments. For example, the definition

```
\newcommand\floor[1]{\left\lfloor {#1} \right\rfloor}
```

produces a flexible floor function $\left\lfloor \frac{3\pi}{2} \right\rfloor$. And yes, the `[1]` can be replaced by `[n]` if you have use for `n` arguments (which get the placeholders `#1`, `#2`, ..., `#n`).

The previous example reminds me to strongly recommend the use of `\left` and `\right` whenever you use parentheses:

$$(\frac{a}{b} - 2) \text{ just doesn't look good compared with } \left(\frac{a}{b} - 2 \right).$$

There are three dashes in LATEX—one like the one you just saw, one that's used in "Berndt–Zaharescu's Theorem" or "Chapter 7–9," and one that's used in "well-known identity."

One of my favorite packages is `enumerate`:

  i) first item

 ii) second item

iii) third item

iv) ...

> TO DO: I stole the idea of a to-do box from a friend. This is useful when editing a paper and you want to remind your co-author or yourself about something...

3.2   Math

You can put a □ at the end of a math line if a proof happens to end with a math line. The version...

Proof. This follows from

$$e^{2\pi i} = 1 \,.$$

□

...wastes space and doesn't look nearly as cool as...

Proof. This follows from

$$e^{2\pi i} = 1 \,. \qquad \square$$

Speaking about proofs, sometimes you need a paragraph or two between a theorem and its proof, in which case you can use...

Proof of Theorem 3.1. This follows from

$$e^{2\pi i} = 1 \,. \qquad \square$$

You can (and should) define your own math operators with \operatorname. For example,

$$\operatorname{lcm}(2,3) = 6 \text{ looks better than } lcm(2,3) = 6.$$

Speaking about lcm's, I find it amusing that \gcd is a pre-defined operator, whereas \lcm is not.

The \dots command is relatively smart in LaTeX; e.g., it knows automatically where to put the dots in $\{1, 2, \ldots, n\}$ as compared to $1 + 2 + \cdots + n$. If you ever need to force a certain alignment of the dots, use $\ldots$, $\cdots$, $\vdots$, or $\ddots$.

For math stuff that takes several lines I prefer the environment **align** over **eqnarray**. The difference is minor but I still prefer

$$\sum_{j=1}^{k-1} \chi(j) \sin^2\left(\frac{\pi j}{k}\right) \tan\left(\frac{2\pi j}{k}\right) = \sqrt{k}\left(-\frac{1}{2} + (\chi(2) - 2)\,h(-k)\right)$$

$$= \begin{cases} \sqrt{k}\left(-\frac{1}{2} - 3\,h(-k)\right) & \text{if } k \equiv 3 \bmod 8, \\ \sqrt{k}\left(-\frac{1}{2} - h(-k)\right) & \text{if } k \equiv 7 \bmod 8 \end{cases}$$

over

$$\sum_{j=1}^{k-1} \chi(j) \sin^2\left(\frac{\pi j}{k}\right) \tan\left(\frac{2\pi j}{k}\right) = \sqrt{k}\left(-\frac{1}{2} + (\chi(2) - 2)\,h(-k)\right)$$

$$= \begin{cases} \sqrt{k}\left(-\frac{1}{2} - 3\,h(-k)\right) & \text{if } k \equiv 3 \bmod 8, \\ \sqrt{k}\left(-\frac{1}{2} - h(-k)\right) & \text{if } k \equiv 7 \bmod 8. \end{cases}$$

3.3   Graphics

My favorite way to produce graphics is through a (public-domain) program called `jPicEdt`; it produces LaTeX code that can be read right into the file (using the `\input` command). My second favorite way to go about graphics is through the package `graphicx`. I produce my graphics with a separate program, export them into pdf, and then overlay them with TeX symbols if needed; see Figure 3.1 for an example.

Figure 3.1: Proper t-colorings of K_3.

The overlaying of figures reminds me of two of my other favorite LaTeX commands: `\vspace` and `\hspace`. For example, they allow you to place just about

anywhere.

anything

This can be very useful, e.g., for presentations in which you might move pictures around.

3.4   Bibliographic Stuff

For references like [2, Section 2] I recommend using `bibtex`; it means that you have to do only minimal work, especially when you get the entries from *MathSciNet*. I keep all the references I've ever used in the same file and use this in all my documents...

If you could use an index at the end of your document, use `makeindex`—one of best reasons to use LaTeX if you're writing a book.

3.5   A Cantor set with positive Newhouse Thickness is not universal

We say that a set E is *universal* in the collection of dense G_δ sets if for all G_δ set, we can always find some affine copies of E inside the set. By an affine copy, we mean sets of the form $t + \lambda E$ for some $t \in \mathbb{R}$ and $\lambda \neq 0$. A natural question we have is that is there a nowhere dense Cantor Set that is universal in the collection of dense G_δ sets? This is an exploration of an Erdös conjecture in a topological setting.

Theorem 3.2. *Let J be a cantor set with positive Newhouse thickness. Then J is not universal.*

Proof. Suppose we have some Cantor set J with Newhouse thickness $\tau(J) > 0$. Without loss of generality, we can assume the convex hull of J $[0, 1]$. Consider Cantor

sets K defined by contraction ratio $1/N$ and digits $\{0, 1, ..., N-1\} \setminus \{(N-1)/2\}$ and N is odd. By a simple calculation, $\tau(K) = \frac{N-1}{2}$. Therefore, we can find a sufficiently large N so that $\tau(J)\tau(K) > 1$.

Using the Cantor set K Define X such that

$$X = \bigcup_{n \in \mathbb{Z}} \bigcup_{\ell \in \mathbb{Z}} N^n(K + \ell),$$

creating a dense F_σ set. Now consider X^c. Because K^c is open and dense and so is its translated and dilated copies, by the Baire Category Theorem, X^c is a dense G_δ. We now show that X^c contains no affine copy of J.

Suppose we have some affine copy, $t + \lambda J$ where $t \in \mathbb{R}$ and $\lambda \neq 0$. There exists a unique n such that

$$|\lambda| \in (N^{n-1}, N^n]. \tag{3.2}$$

Similarly there exists a unique ℓ such that

$$t \in (\ell N^n, (\ell + 1)N^n]. \tag{3.3}$$

We claim that this affine copy of J has a non-empty intersection with $N^n(K + \ell)$. This is equivalent to showing that

$$t \in N^n(K + \ell) - \lambda J.$$

For consistent notation with a referenced theorem, let

$$C_1 = N^n(K + \ell) \text{ and } C_2 = -\lambda J.$$

First we check the construction of our Cantor sets. For C_1 its largest corresponding open gap interval is $|O_1| = N^{n-1}$ and its largest corresponding closed interval is $|I_1| = N^n$. For C_2 and is corresponding intervals, we find that $|O_2| = |\lambda| \cdot |O_J| \leq |\lambda|$ and $|I_2| = |\lambda|$ where O_J is the largest open gap interval in J. Therefore by our construction in (1) the following two inequalities hold:

$$|O_1| \leq |I_2| \text{ and } |O_2| \leq |I_1|$$

as in the condition of Theorem 2.2.1 in [1]. By [1, Theorem 2.2.1][1], given that the Newhouse thickness of our sets, $\tau(K)\tau(J) \geq 1$ then $C_1 + C_2 = I_1 + I_2$. Note that $I_1 = [\ell N^n, (\ell + 1)N^n]$, $I_2 = [-\lambda, 0]$ if $\lambda > 0$ and $I_2 = [0, -\lambda]$ if $\lambda < 0$. we find that

$$I_1 + I_2 = [N^n \ell - \lambda, N^n(\ell + 1)] \ (\lambda > 0) \text{ and } I_1 + I_2 = [N^n \ell, N^n(\ell + 1) - \lambda](\lambda < 0).$$

Then from (2)

$$t \in I_1 + I_2.$$

---

[1]This might misattribute the theorem. I think Astels '99 Theorem 2.2.1 is actually is quoting Newhouse directly. In particular I think it refers to Newhouse 1979 [3] *The Abundance of Wild Hyperbolic Sets, and Non-smooth Stable Sets for Diffeomorphisms.*

Therefore the affine copy of the cantor set $t + \lambda J$ has a non-empty intersection with X and J cannot be universal.

$\square$

It would be interesting to study those Cantor sets with Newhouse thickness zero. We do not know what would happen. However, it seems like if we assume a weaker condition on J.

$(*)$: There exists K such that $J + K = I_J + I_K$, where I_J, I_K are the smallest closed interval containing J and K.

we may be able to show that J cannot be universal for dense G_δ sets.

3.6   Current Research Questions: Zero Newhouse Thickness

This section is devoted to study if Cantor sets with zero Newhouse thickness can be universal. We first provide an example for which two Cantor sets with zero Newhouse thickness can still have arithmetic sum equal to an interval, showing that the converse of theNewhouse thickness theorem us not true.

Example 3.1. Let $N_1, N_2, \cdots \in \mathbb{N}_{\geq 2}$. Consider the following construction of a Cantor set using a decomposition of the unit intervals.

$$
\begin{aligned}
[0, 1] &= \frac{1}{N_1}\{0, 1, \ldots, N_1 - 1\} + \left[0, \frac{1}{N_1}\right] \\
&= \frac{1}{N_1}\{0, 1, \ldots, N_1 - 1\} + \frac{1}{N_1 N_2}\{0, 1, \ldots, N_2 - 1\} + \left[0, \frac{1}{N_1 N_2}\right] \\
&= \ldots \\
&= \frac{1}{N_1}\{0, 1, \ldots, N_1 - 1\} + \frac{1}{N_1 N_2}\{0, 1, \ldots, N_2 - 1\} + \cdots + \frac{1}{N_1 \cdots N_n}\{0, \ldots, N_n\} + \ldots
\end{aligned}
$$

From here we can define the two cantor sets K_1, K_2 where K_1 constitutes the odd indices sets in the above summands and K_2 has the even one. This gives the following constructions for the two Cantor sets:

$$
K_1 = \frac{1}{N_1}\{0, 1, \ldots, N_1 - 1\} + \cdots + \frac{1}{N_1 \cdots N_{2n+1}}\{0, \ldots, N_{2n+1} - 1\} + \ldots
$$

$$
K_2 = \frac{1}{N_1 N_2}\{0, 1, \ldots, N_2 - 1\} + \cdots + \frac{1}{N_1 \cdots N_{2n}}\{0, \ldots, N_{2n} - 1\} + \ldots
$$

From this construction we see that $K_1 + K_2 = [0, 1]$ is the interval but from the definition of Newhouse thickness,

$$
\tau(K_1) = \inf \left\{ \frac{1}{N_1 - 1}, \frac{1}{N_3 - 1}, \ldots \right\} = 0
$$

$$
\tau(K_2) = \inf \left\{ \frac{1}{N_2 - 1}, \frac{1}{N_4 - 1}, \ldots \right\} = 0.
$$

Therefore we have created an interval from two sets with Newhouse thickness 0 if we have $\lim_{n\to\infty} N_n = \infty$.

We ask the following questions. Recall I_J denotes the smallest closed interval containing the Cantor set J and O_J denotes the largest open interval in $I_J \setminus J$.

1. Given a Cantor set J, does there exist some K such that $J + K = I_J + I_K$?

2. If we assume that there exists K such that $J + K = I_j + I_K$, can we prove that J is not universal?

3. (rescaling condition) If we assume that $|\lambda_1 I_J| \geq |\lambda_2 O_K|, |\lambda_2 I_K| \geq |\lambda_1 O_J|$ and $J + K = I_J + I_K$, then $\lambda_1 J + \lambda_2 K = \lambda_1 I_J + \lambda_2 I_k$.

We also notice that to solve the second question, we notice that $J + K = I_J + I_K$ implies that

$$(J + a) + (K + b) = (I_J + a) + (I_K + b) \text{ and } bJ + bK = bI_J + bI_K.$$

We can always translate and rescale J, K so that $I_J = [0, a]$ and $I_K = [0, 1]$. Moreover, the following lemma is important.

Lemma 3.3. *Suppose that the Cantor sets J and K satisfies $J + K = I_j + I_K$. Then $|I_J| \geq |O_K|$ and $|I_K| \geq |O_J|$.*

The lemma also said that the condition $|\lambda_1 I_J| \geq |\lambda_2 O_k|, |\lambda_2 I_k| \geq |\lambda_1 O_J|$ is necessary in the rescaling condition.

Proposition 3.4. *Let J be a Cantor set such that $J+K = I_J+I_K$ where $I_J = [0, a]$ and $I_K = [0, 1]$. Suppose that the rescaling condition (3) holds. Then J is not universal in the collection of dense G_δ.*

Proof. The proof is similar to the proof in Theorem 3.2. With K given in the assumption. We can assume that $|I_J| > |O_K|$. Suppose that $|I_J| = |O_K|$. Since $|O_J| < 1$, we can choose ϵ such that $(1-\epsilon) > |O_J|$. Then we consider $K' = (1-\epsilon)K$ and we will have $|I_J| > (1-\epsilon)|O_K|$. In this case, by the rescaling condition, $J + K' = I_J + I_{K'}$ and we have another K' such that $|I_J| > |O_{K'}|$.

As now we have $|I_J| > |O_K|$, we can find $0 < \rho < 1$ such that $\rho|I_J| > |O_K|$. We now define

$$X = \bigcup_{n \in \mathbb{Z}} \bigcup_{\ell \in \mathbb{Z}} \rho^n(K + \ell).$$

Then X^c is a dense G_δ set. Suppose that we have an affine copy $t + \lambda J$, we would like to claim that $t + \lambda J$ intersects non-trivially with $\rho^n(K + \ell)$ for some $n, \ell \in \mathbb{Z}$, which will complete the proof of the theorem.

To justify the claim, we let $0 < \rho < 1$ take the unique n such that

$$|\lambda| \in [\rho^{n+1}, \rho^n) \tag{3.4}$$

and the unique $\ell \in \mathbb{Z}$ such that

$$t \in (\ell \rho^n, (\ell + 1)\rho^n]. \tag{3.5}$$

Then we consider the arithmetic sum $\rho^n K - \lambda J$. We now check the assumption in the rescaling condition with $\lambda_1 = \rho^n$ and $\lambda_2 = -\lambda$. Indeed,

$$|\lambda_2 I_J| \geq \rho^{n+1}|I_J| = |\lambda_1|(\rho|I_J|) \geq |\lambda_1 O_K|$$

by our choice of ρ. On the other hand,

$$|\lambda_1 I_K| \geq |\lambda| \geq |\lambda_2 O_J|$$

since $|I_K| \geq |O_J|$ by Lemma 3.3. Hence, using the rescaling condition,

$$\rho^n K - \lambda J = \rho^n I_K - \lambda I_J.$$

If $\lambda > 0$, then we have

$$\rho^n(K + \ell) - \lambda J = [\rho^n \ell - \lambda a, \rho^n(1 + \ell)]$$

which contains t by (3.5). Similarly, if $\lambda < 0$, then

$$\rho^n(K + \ell) - \lambda J = [\rho^n \ell, \rho^n(\ell + 1) - \lambda a].$$

It also contains t by (3.5). The proof is now complete. □

****

From these questions we have several difficulties associated with each. For the first item it is not always clear which cantor sets can be added to each other. Similarly it is difficult to construct a complementing Cantor set because of the difficulties tracking the notation for the different possible open intervals. There maybe some existing tools. It may also just be messy.

For the second point, our proof inherently relies on appropriately selecting a scalar and translation that corresponds to a regular (or fairly regular) Cantor set. In this instance we have to find pick the appropriate λ, t based off of a set of associated intervals that are not uniform. Our proof relies on using the regularity to specify where the intersection is.

A current tool we are exploring is tracking how scaling and translating the collection of intervals $\{O_j\}_{j \in \mathbb{N}}$ by some appropriate bound M such that we can scale our cantor set by $\frac{1}{M^d}$, and demonstrate an appropriate intersection with X^c.

The last question we discussed for the day focused on how scaling Cantor sets, and scaling intervals are interrelated. With Newhouse thickness, because it relies off

of the ratios of $\frac{I_j}{O_{j-1}}$ the scaling factor drops out. Unfortunately if we are considering Cantor sets with Newhouse thickness 0, then there is no corresponding Cantor set with infinite Newhouse thickness. The issue is that from the theorem, the thickness is the product of the two sets so for any finite thickness $0 \cdot \tau(C) = 0$. Therefore Newhouse thickness will not be enough to describe the appropriate construction of the interval. There are a few workarounds that might be possible. In Astels' paper[1] there is a generalized for for countably many cantor sets. Similarly we might be able to find another characterization (measure, dimension etc) of the set, to appropriately find λ and or, another way to combine the two intervals, such that we have a non-empty intersection with X^c.

Appendix A: Triangulations of Polytopes

This creates an appendix, which is not numbered (and therefore has to be added to the table of contents semi-manually).

For code, the `verbatim` environment (maybe in conjunction with `\include`) is helpful:

```
It reproduces text
  exactly
    as
      it
        is
typed.
```

Good luck and enjoy writing!
